## Computer Controlled Radio

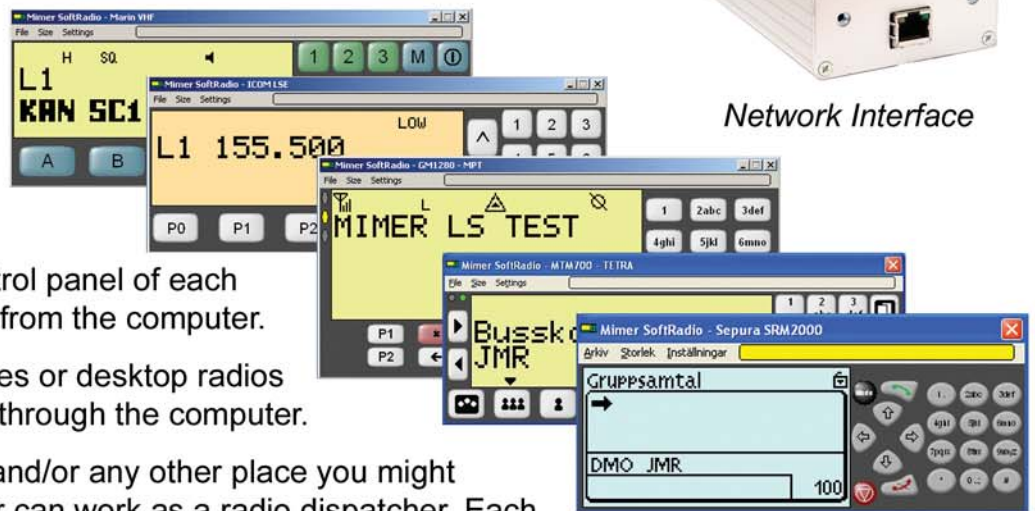

Mimer SoftRadio is a system for control of two-way radio systems over a network or over the Internet.

A Network Interface is connected to the radio. All audio is digitised and sent over the network in packages.

The user then operates the radio via a windows application on his computer.

Network Interface

When needed, the control panel of each radio can be accessed from the computer.

The need for leased lines or desktop radios disappears, all is done through the computer.

At the dispatch center and/or any other place you might need it, every computer can work as a radio dispatcher. Each operator can control several radios and each radio can be controlled by several operators.

Apart from the radio itself, only a small Network Interface is needed. **All** types of radio can be connected, both analogue and digital, from simplex to trunked.

Customized systems are available for special needs, with many communication paths, for example command and control vehicles for the Police or Fire Department, or for large ships.

# Mimer SoftRadio

There is a system configuration for almost every radio user.

**For the small company** - access your local radio over the office LAN. From one or more computers.

**For the large dispatch central** - access both local and remote radios over both local LAN and the Internet. Add on status logging and voice logging.
